Divide and Conquer

Partition

Combine
Parallelization Challenges

• How do we assign work units to workers?
• What if we have more work units than workers?
• What if workers need to share partial results?
• How do we aggregate partial results?
• How do we know all the workers have finished?
• What if workers die?
Common Theme?

• Parallelization problems arise from:
  – Communication between workers (e.g., to exchange state)
  – Access to shared resources (e.g., data)

• Thus, we need a **synchronization** mechanism
Managing Multiple Workers

• Difficult because
  – We don’t know the order in which workers run
  – We don’t know when workers interrupt each other
  – We don’t know the order in which workers access shared data
Managing Multiple Workers

• Thus, we need:
  – semaphores (lock, unlock)
  – conditional variables (wait, notify, broadcast)
  – barriers

• Still, lots of problems:
  – deadlock, livelock, race conditions...
  – dining philosophers, sleeping barbers, cigarette smokers...

• Moral of the story: be careful!
Current Tools

• Programming models
  – Shared Memory (pthreads)
  – Message Passing (MPI)
Current Tools

- Design Patterns
  - Master-Slaves
  - Producer-Consumer Flows
  - Shared Work Queues
Where the rubber meets the road

• Concurrency is difficult to reason about
• Concurrency is even more difficult to reason about
  – At the scale of datacenters (even across datacenters)
  – In the presence of failures
  – In terms of multiple interacting services
• Not to mention debugging...
Where the rubber meets the road

• The reality:
  – Lots of one-off solutions, custom code
  – Write you own dedicated library, then program with it
  – Burden on the programmer to explicitly manage everything
Fallacies of Distributed Computing

• The network is reliable.
• Latency is zero.
• Bandwidth is infinite.
• The network is secure.
• Topology doesn't change.
• There is one administrator.
• Transport cost is zero.
• The network is homogeneous.
What’s the point?

• It’s all about the right level of abstraction
  – The von Neumann architecture has served us well, but is no longer appropriate for the multi-core or cluster environment.

The datacenter is the computer!
What’s the point?

• Hide system-level details from the developers
  – No more race conditions, lock contention, etc.
• Separating the *what* from *how*
  – Developer specifies the computation that needs to be performed
  – Execution framework (“runtime”) handles actual execution
“Big Ideas”

• *Scale “out”, not “up”*
  – Limits of SMP and large shared-memory machines

• *Move processing to the data*
  – Cluster have limited bandwidth

• *Process data sequentially, avoid random access*
  – Seeks are expensive, disk throughput is reasonable

• *Seamless scalability*
  – From mythical man-month to tradable machine-hour
Warm-Up

• The task:
  – We have a huge text document
  – Count the number of times each distinct word appears in the file

• Sample application:
  – Analyse web server logs to find popular URLs
Warm-Up

• In UNIX, it can be easily done:

```
words(doc.txt) | sort | uniq -c
```

– Here `words` is a script that takes a file and outputs the words in it, one per a line.
– The file `doc.txt` may be too large for memory, but all `<word, count>` pairs fit in memory
– The great thing is that it is naturally parallelizable
– This captures the essence of MapReduce
Typical Big-Data Problem

- Iterate over a large number of records
- Extract something of interest from each
- Shuffle and sort intermediate results
- Aggregate intermediate results
- Generate final output

Key idea: provide a functional abstraction for these two operations

(Dean and Ghemawat, OSDI 2004)
1. Who here is pro-gay and/or pro-abortion?

<table>
<thead>
<tr>
<th>John Smith</th>
<th>Pro-Gay</th>
<th>Pro-Abortion</th>

</tr>
</tbody>
</table>

2. All people pro-gay and/or pro-abortion get this hashcode.

3. Same hashcode many people

   Hash Code

   From: [Hash Code]

   To: [Envelope]

   PLAN OF ACTION:

   Send customized email to the people with the same hashcode.

Source: Hadoop Illuminated
MapReduce overview

• Read a lot of data, sequentially
• **Map:**
  – Extract something you care about
• **Shuffle and Sort**
  – Group by key
• **Reduce:**
  – Aggregate, summarize, filter or transform
• Write the result

Outline stays the same, **map** and **reduce** change to fit the problem.
The **Map Step**
The **Reduce** Step

Intermediate key-value pairs

key-value groups

Output key-value pairs

Intermediate key-value pairs

key-value groups

Output key-value pairs
Roots in *Functional Programming*
Shuffle and Sort: aggregate values by keys

- a: 1 5
- b: 2 7
- c: 2 3 6 8

reduce

- r1: s1
- r2: s2
- r3: s3
MapReduce Programming Model

• Programmers must specify two functions:
  \[ \text{map} \ (k, v) \rightarrow <k', v'>^* \]
    • Takes a key value pair and outputs a set of key value pairs, e.g., key = filename, value = the file content
    • There is one Map call for every (k,v) pair
  \[ \text{reduce} \ (k', <v'>^*) \rightarrow <k', v'''>^* \]
    • All values \( v' \) with same key \( k' \) are reduced together and processed in \( v' \) order
    • There is one Reduce function call per unique key \( k' \)

• The execution framework handles everything else
MAP: reads input and produces a set of key value pairs

Group by key: Collect all pairs with the same key

Reduce: Collect all values belonging to the key and output
Execution in Parallel

Map Task 1

Partitioning Function

Map Task 2

Partitioning Function

Map Task 3

Partitioning Function

Sort and Group

Reduce Task 1

Sort and Group

Reduce Task 2
Two More Details...

• Barrier between map and reduce phases
  – But we can begin copying intermediate data earlier

• Keys arrive at each reducer in sorted order
  – No enforced ordering across reducers
“Hello World”: Word Count

Provided by the programmer

**MAP:**
reads input and produces a set of key value pairs

- (the, 1)
- (crew, 1)
- (of, 1)
- (the, 1)
- (space, 1)
- (shuttle, 1)
- (Endeavor, 1)
- (recently, 1)

Provided by the programmer

**Group by key:**
Collect all pairs with same key

- (crew, 1)
- (crew, 1)
- (space, 1)
- (the, 1)
- (the, 1)
- (shuttle, 1)
- (recently, 1)

Provided by the programmer

**Reduce:**
Collect all values belonging to the key and output

- (crew, 2)
- (space, 1)
- (the, 3)
- (shuttle, 1)
- (recently, 1)
- ...

Only sequential reads
“Hello World”: Word Count

map(key, value):
// key: document name; value: text of the document
    for each word w in value:
        emit(w, 1)

reduce(key, values):
// key: a word; values: an iterator over counts
    result = 0
    for each count v in values:
        result += v
    emit(key, result)
“Hello World”: Word Count

Input: the quick brown fox, the fox ate the mouse, how now brown cow

Map: the, 1 brown, 1 fox, 1
Shuffle & Sort: quick, 1
Reduce: brown, 2 fox, 2 how, 1 now, 1 the, 3

Output: ate, 1 cow, 1 mouse, 1 quick, 1
Exercise

• Information Retrieval (TFxIDF):
  – Given a large document collection, for every word, we need to count the number of documents containing it (i.e., document frequency)

• Statistical Machine Translation (5-gram):
  – Given a large document collection, for every 5-word sequence, we need to count the number of times it occurs in the whole collection
What’s “everything else”? 

• MapReduce “runtime” environment handles
  – **scheduling**: assigns workers to map and reduce tasks
  – **data distribution**: partitions the input data and moves processes to data
  – **synchronization**: manages required inter-machine communication to gather, sort, and shuffle intermediate data
  – **errors and faults**: detects worker failures and restarts

*Everything happens on top of a DFS*
Data Flow

• The input and final output are stored on a distributed file system
  – Scheduler tries to schedule map tasks “close” to physical storage location of input data

• The intermediate results are stored on the local file system of map and reduce workers

• The output is often the input to another MapReduce task
Coordination

- Master keeps an eye on each task’s status: (idle, in-progress, completed)
  - Idle tasks get scheduled as workers become available
  - When a map task completes, it sends Master the location and sizes of its $R$ intermediate files, one for each reducer, and then Master pushes this info to reducers
  - Master pings workers periodically to detect failures
Dealing with Failures

• Map worker failure
  – Map tasks completed or in-progress at worker are reset to idle
  – Reduce workers are notified when task is rescheduled on another worker

• Reduce worker failure
  – Only in-progress tasks are reset to idle

• Master failure
  – MapReduce task is aborted and client is notified
How many Map and Reduce tasks?

• $M$ map tasks, $R$ reduce tasks
• Rule of a thumb:
  – Make $M$ and $R$ much larger than the number of nodes in cluster
  – One DFS chunk per map is common
  – Improves dynamic load balancing and speeds recovery from worker failure
• Usually $R$ is smaller than $M$
  – because output is spread across $R$ files
Task Granularity

- Fine granularity tasks: map tasks >> machines
  - Minimizes time for fault recovery
  - Can pipeline shuffling with map execution
  - Better dynamic load balancing
Refinement: Combine & Partition

• Really, “everything else”?
• Not quite... often, programmers also specify:
  \[\text{combine} \ (k', v') \rightarrow <k', v'>^*\]
    • Mini-reducers that run in memory after the map phase
    • Used as an optimization to reduce network traffic
  \[\text{partition} \ (k', \#\text{partitions}) \rightarrow \text{partition for } k'\]
    • Often a simple hash of the key, e.g., hash(k') mod n
    • Divides up key space for parallel reduce operations
Combine Function

• A map task can produce many pairs with the same key: (k,v1), (k,v2), ...
  – e.g., popular words in the WordCount example
  – They need to be sent over the network to the reducer: costly

• It is often possible to pre-aggregate these pairs into a single key-value pair at the mapper
  – Decreases the size of intermediate data and thus save network time
Combine Function

• The combiner is executed to combine the values for a given key
  – e.g., (jaguar,1), (jaguar, 1), (jaguar, 1), (jaguar, 2) → (jaguar, 5)
  – The combiner can be called several times, or not at all
• Easy case: the combine function is the same as the reduce function
  – Works only if the reduce function is commutative and associative.
Word Count with *Combine*

The diagram illustrates the process of word counting using a map-reduce algorithm. Here's a breakdown of the steps:

**Input:**
- "the quick brown fox"
- "the fox ate the mouse"
- "how now brown cow"

**Map & Combine:**
- Multiple maps process the input sentences.
  - For "the quick brown fox":
    - Output: "the, 1"
    - "brown, 1"
    - "fox, 1"
  - For "the fox ate the mouse":
    - Output: "the, 2"
    - "fox, 1"
    - "ate, 1"
    - "mouse, 1"
  - For "how now brown cow":
    - Output: "how, 1"
    - "now, 1"
    - "brown, 1"
    - "cow, 1"

**Shuffle & Sort:**
- The outputs are shuffled and sorted to group similar words together.

**Reduce:**
- The reduce phase aggregates the counts of each word.
  - "the, 3"
  - "fox, 2"
  - "brown, 2"
  - "how, 1"
  - "now, 1"
  - "ate, 1"
  - "cow, 1"
  - "mouse, 1"
  - "quick, 1"

**Output:**
- The final output shows the word counts:
  - "brown, 2"
  - "fox, 2"
  - "how, 1"
  - "now, 1"
  - "the, 3"
  - "ate, 1"
  - "cow, 1"
  - "mouse, 1"
  - "quick, 1"
Partition Function

- Inputs to map tasks are simply created by contiguous splits of input file, but reduce tasks need to ensure that records with the same intermediate key end up at the same worker.
  - System uses a default partition function: $\text{hash(key)} \mod R$
  - Sometimes useful to override: e.g., $\text{hash(hostname(URL))} \mod R$ ensures URLs from one host end up in the same output file.
Shuffle and Sort: aggregate values by keys

a 1 5, b 2 7, c 2 9 6 8

reduce

r₁ s₁, r₂ s₂, r₃ s₃
Optimisation: Compression

• Data transfers over the network:
  – From datanodes to mapper nodes (usually reduced using data locality)
  – From mappers to reducers
  – From reducers to datanodes to store the final output

• Each of these can benefit from compression
  – Trade-off between the volume of data transfer and the (de)compression time.
  – Usually, compressing map outputs using a fast compressor increases efficiency
Optimisation: Shuffle and Sort

• Sorting of pairs on each reducer to compute the groups is a costly operation
• It would be much more efficient in memory than on disk
  – Increasing the amount of memory available for shuffle operations can greatly increase the performance
  – . . . at the downside of less memory available for map and reduce tasks (but usually not much needed)
Optimisation: Speculative Execution

• The MapReduce jobtracker tries detecting tasks that take longer than usual
  – e.g., because of hardware problems
• When detected, such a task is *speculatively* executed on another tasktracker, without killing the existing task
• Eventually, when one of the attempts succeeds, the other one is killed
Optimisation: Backup Tasks

• Problem: Slow workers significantly lengthen the job completion time
  – Other jobs on the machine
  – Bad disks
  – Weird things

• Solution: Near end of phase, spawn backup copies of tasks. Whichever one finishes first “wins”

• Effect: Dramatically shortens job completion time
MapReduce can refer to...

- The programming model
- The execution framework (aka “runtime”)
- The specific implementation

Usage is usually clear from the context!
MapReduce Implementations

• Google has a proprietary implementation in C++
  – Bindings in Java, Python

• Hadoop is an open-source implementation in Java
  – Development led by Yahoo, used in production
  – Now an Apache project
  – Rapidly expanding software ecosystem

• Lots of custom research implementations
  – For GPUs, cell processors, etc.
Adapted from (Dean and Ghemawat, OSDI 2004)
Hadoop

• Open-source implementation of Google’s GFS and MapReduce
  – Java-based software
  – Managed by the Apache foundation
  – Originally developed for Apache Nutch (open-source Web search engine), a part of Apache Lucene (text indexing platform)
  – Yahoo! has been a main contributor of the development of Hadoop
Hadoop

• Components
  – Hadoop File System (HDFS)
  – MapReduce
  – Pig (data exploration), Hive (data warehousing): higher-level languages for describing MapReduce applications
  – HBase: column-oriented distributed DBMS
  – ZooKeeper: coordination service for distributed applications
Paper on MapReduce inspires Doug Cutting to create his open source implementation, which names after his son’s toy elephant.

- Doug Cutting joins Yahoo
- Sorts 1.9TB on 188 nodes in 47 hours
- Hadoop gets top-level Apache status
- Wins Terrabyte sort benchmark

- 2004
- 2005
  - Dec
    - Nutch ported to map/reduce
- 2006
  - Jan
    - Factored out of Nutch
  - Feb
  - April
    - Yahoo sets up research cluster
- 2008
  - Jan
  - Feb
  - April
    - Available to integrate with Amazon EC2/S3
  - Aug
    - Runs 4000 node cluster

Hadoop History

• 12/2004 – Google GFS paper published
• 07/2005 – Nutch uses MapReduce
• 02/2006 – Becomes Lucene subproject
• 04/2007 – Yahoo! on 1000-node cluster
• 01/2008 – An Apache Top Level Project
• 07/2008 – A 4000 node test cluster
• 09/2008 – Hive becomes a Hadoop subproject
Hadoop History

• 02/2009 – The Yahoo! Search Webmap is a Hadoop application that runs on more than 10,000 core Linux cluster and produces data that is now used in every Yahoo! Web search query.

• 06/2009 – On June 10, 2009, Yahoo! made available the source code to the version of Hadoop it runs in production.

• xx/2010 – In 2010 Facebook claimed that they have the largest Hadoop cluster in the world with 21 PB of storage. On July 27, 2011 they announced the data has grown to 30 PB.
Who use Hadoop?

• Amazon/A9
• Facebook
• Google
• IBM
• Joost
• Last.fm
• New York Times
• PowerSet
• Veoh
• Yahoo!
• .......

http://wiki.apache.org/hadoop/PoweredBy
- 40 nodes/rack, 1000-4000 nodes in cluster
- 1 GBps bandwidth in rack, 8 GBps out of rack
- Node specs (Yahoo terasort):
  8 x 2.0 GHz cores, 8 GB RAM, 4 disks (= 4 TB?)
Hadoop API

• Different APIs to write Hadoop programs:
  – A rich **Java** API (main way to write Hadoop programs)
  – A Streaming API that can be used to write map and reduce functions in any programming language (using standard inputs and outputs), e.g., in Python
  – A C++ API (Hadoop Pipes)
  – With a higher language level (e.g., Pig, Hive)
Hadoop API

• Mapper
  – void map(K1 key, V1 value, OutputCollector<K2, V2> output, Reporter reporter)
  – void configure(JobConf job)
  – void close() throws IOException

• Reducer/Combiner
  – void reduce(K2 key, Iterator<V2> values, OutputCollector<K3,V3> output, Reporter reporter)
  – void configure(JobConf job)
  – void close() throws IOException

• Partitioner
  – void getPartition(K2 key, V2 value, int numPartitions)

}
Basic Data Types in Hadoop

**Writable**

Defines a de/serialization protocol. Every data type in Hadoop is a Writable.

**WritableComparable**

Defines a sort order. All keys must be of this type (but not values).

**IntWritable**

Concrete classes for different data types.

**LongWritable**

**Text**

**SequenceFiles**

Binary encoded of a sequence of key/value pairs
Complex Data Types in Hadoop

• The easy way:
  – Encoded it as Text, e.g., (a, b) = “a:b”
  – Use regular expressions to parse and extract data
  – Works, but pretty hack-ish
Complex Data Types in Hadoop

• The hard way:
  – Define a custom implementation of `WritableComparable`
  – Must implement: `readFields, write, compareTo`
  – Computationally efficient, but slow for rapid prototyping
A Few Gotchas

• Avoid object creation, at all costs
• Execution framework reuses value in reducer
• Passing parameters into mappers and reducers
  – DistributedCache for larger (static) data
Basic Cluster Components

• One of each:
  – Namenode (NN)
  – Jobtracker (JT)

• Set of each per slave machine:
  – Tasktracker (TT)
  – Datanode (DN)
Putting Everything Together

- namenode
  - namenode daemon
- job submission node
  - jobtracker
- tasktracker
- datanode daemon
- Linux file system
- slave node
  - datanode daemon
  - Linux file system
- slave node
  - datanode daemon
  - Linux file system
- slave node
  - datanode daemon
  - Linux file system
Anatomy of a Job

• MapReduce program in Hadoop = Hadoop job
  – Jobs are divided into map and reduce tasks
  – An instance of running a task is called a task attempt
  – Multiple jobs can be composed into a workflow
Anatomy of a Job

• Job submission process
  – Client (i.e., driver program) creates a job, configures it, and submits it to job tracker
  – JobClient computes input splits (on client end)
  – Job data (jar, configuration XML) are sent to JobTracker
  – JobTracker puts job data in shared location, enqueues tasks
  – TaskTrackers poll for tasks
  – Off to the races...
1. Client wants to run a job
2. Client gets a job id from the job tracker
3. Client copies job resources to HDFS
4. Client submits job to job tracker
5. Client initializes job
6. Job splits
7. Job tracker kicks off job
8. Retrieve job resources
9. Launch child JVM and runs map or reduce
10. Task tracker sends regular heartbeats to job tracker

Happily ever after! (unless the task tracker dies)

Source: Hadoop Illuminated
Input and Output

• InputFormat:
  – TextInputFormat
  – KeyValueTextInputFormat
  – SequenceFileInputFormat
  – ...

• OutputFormat:
  – TextOutputFormat
  – SequenceFileOutputFormat
  – ...

Shuffle and Sort in Hadoop

• Map side
  – Map outputs are buffered in memory in a circular buffer
  – When buffer reaches threshold, contents are “spilled” to disk
  – Spills merged in a single, partitioned file (sorted within each partition): combiner runs here
Shuffle and Sort in Hadoop

• Reduce side
  – First, map outputs are copied over to reducer machine
  – “Sort” is a multi-pass merge of map outputs (happens in memory and on disk): combiner runs here
  – Final merge pass goes directly into reducer
Hadoop Workflow

1. Load data into HDFS
2. Develop code locally
3. Submit MapReduce job
   3a. Go back to Step 2
4. Retrieve data from HDFS

You
On AWS: with EC2

0. Allocate Hadoop cluster
1. Load data into HDFS
2. Develop code locally
3. Submit MapReduce job
3a. Go back to Step 2
4. Retrieve data from HDFS
5. Clean up!

Uh oh. Where did the data go?
On AWS: with EC2 and S3

Copy from S3 to HDFS

EC2
(Cloud Computer)

Your Hadoop Cluster

Copy from HFDS to S3

S3
(Persistent Store)
Testing and Executing a Hadoop job

• Required environment:
  – JDK on client
  – JRE on all Hadoop nodes
  – Hadoop distribution (HDFS + MapReduce) on client and all Hadoop nodes
  – SSH servers on each tasktracker, SSH client on jobtracker (used to control the execution of tasktrackers)
  – An IDE (e.g., Eclipse + plugin) on client
Testing and Executing a Hadoop job

• Three different execution modes:
  – **local**: one mapper, one reducer, run locally from the same JVM as the client
  – **pseudo-distributed**: mappers and reducers are launched on a single machine, but communicate over the network
  – **distributed**: over a cluster for real runs
Testing and Executing a Hadoop job

• Task JVM Reuse
  – By default, each map and reduce task (of a given split) is run in a separate JVM
  – When there is a lot of initialization to be done, or when splits are small, it might be useful to reuse JVMs for subsequent tasks
  – Of course, only works for tasks run on the same node
Testing and Executing a Hadoop job

• Hadoop in the cloud
  – Possibly to set up one’s own Hadoop cluster
  – But often easier to use Hadoop clusters in the cloud that support MapReduce:
    • Amazon EMR etc.
  – Not always easy to know the cluster’s configuration (in terms of racks, etc.) when on the cloud, which hurts data locality in MapReduce
Debugging Hadoop Programs

• First, take a deep breath

• Start small, start locally
  – Debugging in local mode is the easiest
  – Remote debugging possible but complicated to set up (impossible to know in advance where a map or reduce task will be executed)

• Learn to use the Web interface with status information about the job

• Throw RuntimeExceptions
Debugging Hadoop Programs

• Where does println go?
  – Standard output and error channels saved on each node, accessible through the Web interface

• Don’t use println, use logging

• Counters can be used to track side information across a MapReduce job
  – e.g., the number of invalid input records

• IsolationRunner allows to run in isolation part of the MapReduce job
Debugging at Scale

• Your program works on small datasets, but it won’t scale... Why?
  – Memory management issues (object creation and buffering)
  – Too much intermediate data
  – Mangled input records
Debugging at Scale

• Real-world data is messy!
  – For example, WordCount
    • How many unique words there are in Wikipedia?
  – There’s no such thing as “consistent data”
  – Watch out for corner cases
  – Isolate unexpected behavior, bring local
Hadoop Zen

• This is bleeding edge technology (i.e., immature!)
  – Bugs, undocumented features, inexplicable behavior
  – Data loss(!)

• Don’t get frustrated (take a deep breath)...
  – Those W$*#T@F! moments

• RTFM, RTFC
Hadoop Zen

• Be patient ...
  – We will inevitably encounter “situations” along the way

• Be flexible ...
  – We will have to be creative in workarounds

• Be constructive ...
  – Tell me how I can make everyone’s experience better
